EDAC(EcoSystem Data Assembly Center)

EDAC is used to back up data from people who run Ocean Models.

The data is then served using OpenDAP, which allows clients to download only what they need out of Data Set.

Accomplished using THREDDS, which lets clients use data easily.

NGI/NOAA Developmental Ecosystem Data Assembly Center

OceanNOMADS

The NOAA National Weather Service NOAA Operational Model Archive and Distribution System (NOAAMS) provides distributed, web-service access for real-time and retrospective, freely available climate and weather model data and related datasets.

NOAAMS (NGDC/NCEP) creates a real-time operational ocean forecast system called OceanBAM with the real-time ocean forecast output provided via servers at the NCEP Ocean Prediction Center and archival at NGDC via NOAA Comprehensive Large Array Storage System (CLASS). A joint Northern Gulf Institute (NGI) /NOAA effort created the developmental version of the archival OceanBAM capability under the Ecosystem Data Assembly Center (EDAC) project. Access tool development, storage of NOAAMS and Navy ocean prediction capabilities occur on the NGI/NOAAC developmental servers with planned transition to NGDC/NOAAC operational servers as the ocean forecast archive matures and operational space and distribution capacity grows. OceanBAM provides access to ocean prediction system output by both direct download and via OPeNDAP.

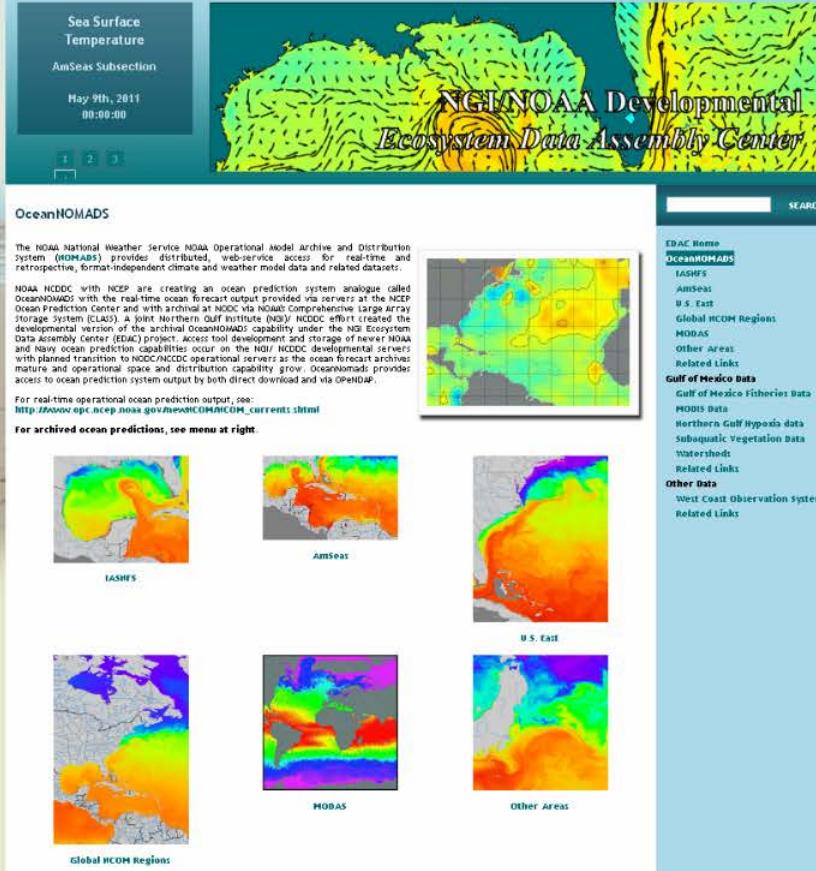

For real-time operational ocean prediction output, see:
http://www.ngdc.noaa.gov/ocm/oceanforecast_currents.shtml

For archived ocean predictions, see menu at right.

Problem Background

The problem that my project is intended to fix is the difficulty of keeping track of the constant download of NCOM data. The sheer number of files makes it difficult to verify all possible problems manually, making it all too easy to miss bad files, partial downloads, and valid files that contain faulty data.

System Administrator is not notified when these problems occur.

Sample Of Work

Program Detects :

- Bad Files
- Missing Files
- Time Gaps
- Redundant Files

```
#!/usr/bin/python

# This program is designed to search for specific file types in a directory and its sub-directories.
# It then creates a JSON file containing the paths of found files.
# The user can specify the file type and the output file name.

# Import required modules
import os
import json
from collections import defaultdict

# Set the file type to search for
file_type = "txt"

# Set the output file name
output_file = "found_files.json"

# Set the directory to search
directory_path = "/path/to/search"

# Initialize a dictionary to store found files
found_files = defaultdict(list)

# Recursively search for files of the specified type
for root, dirs, files in os.walk(directory_path):
    for file in files:
        if file.endswith(file_type):
            found_files[root].append(os.path.join(root, file))

# Create a JSON file with the found files
with open(output_file, "w") as f:
    json.dump(found_files, f, indent=4)
```

        jsondi["badlength"].append(files[each]+ " " + str(file_size[each]));
    #    print "Size of %s is %d"%(files[each],file_size[each]) + '\n';
    #    htmlfile.write("Size of %s is %d"%(files[each],file_size[each]) + '\n<br />');
        badfile.write("Size of %s is %d"%(files[each],str(file_size[each])) + '\n');
```

Results

The output of my program writes to a HTML file.
